Nurses
Occupational Therapists
Physical Therapists
Physician Assistants
Physicians

GUIDELINE OBJECTIVE(S)

To promote the appropriate use of therapeutic exercises and manual therapy in the management of rheumatoid arthritis

TARGET POPULATION

Adult patients (18 years of age) with a diagnosis of rheumatoid arthritis (RA) according to the 1987 American Rheumatism Association (ARA) criteria.

A patient was said to have RA if he or she satisfied at least 4 of the following 7 ARA criteria:

- Morning stiffness
- Arthritis of 3 or more joints
- Arthritis of the hand joints
- Symmetric arthritis
- Rheumatoid nodules
- Serum rheumatoid factor
- Radiologic changes

Patients with RA affecting peripheral joints and patients with both chronic and acute RA are included.

Excluded groups include: Patients with RA who have back or neck problems; patients who have recently had surgery; and patients who have one of the following conditions: (1) other rheumatologic or musculoskeletal problems, such as tendinitis, bursitis, or fractures; (2) major medical problems that could interfere with the rehabilitation process or incapacitate functional status; or (3) psychiatric conditions. Subjects without known pathology or impairments also are excluded.

INTERVENTIONS AND PRACTICES CONSIDERED

Therapeutic Exercises

1. Physical activity

2. Specific functional strengthening exercises
3. Whole-body functional strengthening exercises
 - Low intensity
 - High intensity

Note: Manual therapy (defined as passive physiologic and accessory joints movements, muscle stretching, and soft tissue mobilizations applied to a specific joint) was considered but no recommendations were made because no acceptable evidence was identified.

MAJOR OUTCOMES CONSIDERED

Organ Systems and Impairment

- Number of inflamed joints
- Number of acute phase reactants (e.g., erythrocyte sedimentation rate)
- Radiological damage
- Side effects

Abilities and Disabilities

- Pain reduction
- Muscle force
- Range of motion (ROM)
- Postural status
- Duration of morning stiffness

Life Habits and Handicap Situation

- Global physician assessment
- Global patient assessment
- Gait status
- Walking speed
- Walking distance
- Cadence
- Stride length
- Functional status
- Patient adherence
- Patient satisfaction
- Length of stay
- Discharge disposition
- Quality of life
- Return to work

METHODOLOGY

METHODS USED TO COLLECT/SELECT EVIDENCE

Hand-searches of Published Literature (Primary Sources)
 Searches of Electronic Databases

DESCRIPTION OF METHODS USED TO COLLECT/SELECT THE EVIDENCE

The library scientist developed a structured literature search based on the sensitive search strategy for randomized controlled trials (RCTs)--a strategy recommended by The Cochrane Collaboration with modifications to that strategy. The Cochrane Collaboration method minimizes bias through a systematic approach to the literature search, study selection, and data extraction and synthesis. The search was organized around the condition and interventions rather than the outcomes because it was an a priori search. Thus, the guideline developers had no control over the outcomes the authors decided to measure (see Appendix 2 of the original guideline document for an example of the search strategy).

The library scientist expanded the search strategy to identify case-control, cohort, and nonrandomized studies and conducted the search in the electronic databases of MEDLINE, EMBASE, Current Contents, the Cumulative Index to Nursing and Allied Health (CINAHL), and the Cochrane Controlled Trials Register up to December 2002. Also searched were the registries of the Cochrane Field of Rehabilitation and Related Therapies, the Cochrane Musculoskeletal Group, the Physiotherapy Evidence Database (PEDro), and the University of Ottawa Evidence-Based Clinical Practice Guidelines (EBCPGs) Web site. Finally, reference lists of all of the included trials were searched for relevant studies, and content experts were contacted for additional studies.

In the first round of study inclusion or exclusion, 2 independent reviewers, trained and experienced occupational therapist or physical therapist students, appraised the titles and abstracts of the literature search using a checklist with the a priori-defined selection criteria (see Table 1 in the original guideline document). More junior students were paired with fourth-year occupational therapist or physical therapist students who were experienced with the Philadelphia Panel methodology. Each pair of reviewers was assigned to a specific intervention. Within each pair of reviewers, individuals independently read the title and abstract of each article and created an individual list of all of the articles of the database with a reason for including or excluding each article. If the reviewers were uncertain about a particular article after having read the abstract, they ordered the article and read it in full before making a determination. Before deciding whether to include or exclude the article, a comparison of their individual lists was performed. A senior reviewer who is a methodologist and a clinical expert in arthritis checked the 2 independent lists of articles and the reason for inclusion or exclusion to determine potential inconsistencies. Eleven percent of the abstracts reviewed needed the consultation of the senior reviewer. For the second round of inclusion and exclusion, the pairs of reviewers retrieved articles selected for inclusion from the first round and independently assessed the full articles for inclusion or exclusion in the study.

Study Inclusion/Exclusion Criteria

The inclusion/exclusion criteria were based on previous criteria used by the Philadelphia Panel. This list of criteria, which had been created for multiple diagnoses, including back and neck pain, was adapted and approved by the Ottawa Methods Group (OMG) for use with rheumatoid arthritis (RA), (see Table 1 in the original guideline document).

All original comparative controlled studies that evaluated the specific intervention in a sample of patients with RA were included: RCTs, controlled clinical trials (CCTs), cohort studies, and case-control studies. (Controlled clinical trials are the same as RCTs except that, according to the Jadad scale, CCTs are either not randomized or poorly randomized.) Crossover studies were included, and, to avoid potential confounders, the data from only the first part of the study (before crossing) were analyzed. (Data from the first part are more specific than data from the second part because once the study patients change from the intervention group to the placebo group, the outcome could be due to either the intervention or the placebo. Thus, such results are not useful for measuring the special effect of each intervention.)

Uncontrolled cohort studies (studies with no comparison group) and case series were excluded, as were eligible studies with greater than 20% dropout rates or a sample size of less than 5 patients per group. Abstracts were excluded because none of the abstracts found had sufficient data for analysis and the full studies of the abstracts could not be obtained from the authors. Trials published in languages other than French and English were not analyzed because of the time and cost involved in translation. Head-to-head studies (that is, the comparison of 2 active interventions, such as therapeutic exercises versus transcutaneous electrical nerve stimulation) were generally excluded in these recommendations. Because the guideline panel was interested in making a recommendation specifically about therapeutic exercise or manual therapy, they rejected head-to-head studies. At the meeting, the Ottawa Panel recommended that a direct comparison of the intervention with either placebo or control was more valid for measuring the specific effect of the intervention. Included, however, were studies with head-to-head comparisons of high- versus low-intensity exercise as highly relevant for rheumatology practice in rehabilitation, especially in the presence of an inflammatory disease such as RA, where the dosage and intensity of therapy could make a difference in pain tolerance and joint damage. For further exclusion criteria, see Table 1 of the original guideline document.

NUMBER OF SOURCE DOCUMENTS

16 articles relating to therapeutic exercise met the selection criteria and were included.

METHODS USED TO ASSESS THE QUALITY AND STRENGTH OF THE EVIDENCE

Expert Consensus
Weighting According to a Rating Scheme (Scheme Given)

RATING SCHEME FOR THE STRENGTH OF THE EVIDENCE

The methodological quality of the trials was assessed using the Jadad scale, a 5-point scale with reported reliability and validity that assigns 2 points each for randomization and double blinding and 1 point for description of withdrawals.

METHODS USED TO ANALYZE THE EVIDENCE

DESCRIPTION OF THE METHODS USED TO ANALYZE THE EVIDENCE

Data Extraction

Using predetermined extraction forms, the pairs of reviewers independently extracted data from included articles on the population characteristics, details of the interventions, trial design, allocation concealment, and outcomes. The pairs of reviewers assessed methodological quality using the Jadad scale, a 5-point scale with reported reliability and validity that assigns 2 points each for randomization and double blinding and 1 point for description of withdrawals. The reviewers resolved differences in data extraction and quality assessment through consensus with the senior reviewer. This consensus served to support the reliability of data obtained with the article selection process.

Statistical Analysis

Data were analyzed using Review Manager software. Continuous data, "data with a potentially infinite number of possible values along a continuum," were analyzed using the weighted mean differences (WMDs) between the intervention and control groups at the end of the study, where the weight is the inverse of the variance. A WMD is "a method of meta-analysis used to combine measures on continuous scales (such as weight), where the mean, standard deviation, and sample size in each group are known." Dichotomous data, or data with only 2 classifications, were analyzed using relative risks. According to Cochrane, the relative risk is "the ratio of risk in the intervention group to the risk in the control group. The risk (proportion, probability, or rate) is the ratio of people with an event in a group to the total in the group."

Heterogeneity (i.e., variability or difference between studies) was tested using the chi-square statistic. The guideline panel tested data heterogeneity among the results of different included studies to make sure that only homogeneous data were pooled together. When heterogeneity was not significant, fixed-effect models were used. A fixed-effect model is a statistical model that stipulates that the units under analysis (e.g., participants in a meta-analysis study) are the ones of interest and thus constitute the entire population of units. Fixed-effect models were used to generalize data across the included studies. Random effects models include both within-study sampling error (variance) and between-studies variation in the assessment of the uncertainty (confidence interval) of a meta-analysis' results and are more severe than fixed effect models. Such random-effects models were used when heterogeneity was significant. All figures were created using Cochrane Collaboration methodology (www.cochrane.org).

Based on previous studies in the musculoskeletal domain and on consensus, clinical improvement for all interventions studied by the Ottawa Panel was defined as 15% improvement relative to a control. This figure can be justified because it was developed by the Philadelphia Panel, whose members are experts in musculoskeletal practice, and confirmed by another panel (the Ottawa Panel) whose members included specialists in rheumatology and an expert biostatistician.

To determine clinical improvement, the absolute benefit and relative difference in the change from baseline were calculated. Absolute benefit was calculated as the improvement in the treatment group less the improvement in the control group, maintaining the original units of measurement. Relative difference was calculated as the absolute benefit divided by the baseline mean (weighted for the intervention and control groups). For dichotomous data, the relative percentage of improvement was calculated as the difference in the percentage of improvement between the intervention and control groups.

METHODS USED TO FORMULATE THE RECOMMENDATIONS

Expert Consensus

DESCRIPTION OF METHODS USED TO FORMULATE THE RECOMMENDATIONS

The development process of these evidence-based practice guidelines (EBCPGs) was similar to that of the Philadelphia Panel, except that a different target population was used. Briefly, the Ottawa Methods Group (OMG), a group of 9 methodologists with experience in developing EBCPGs, asked professional associations interested in the care of people with rheumatoid arthritis (RA) for suggestions of individuals with both clinical expertise in the management of the disease and familiarity with EBCPGs. From among the suggestions given, the OMG chose 9 experts to serve as panel members. These experts in RA were a rheumatologist, a physiatrist, a physician with experience in evidence-based medicine, a family physician, 3 physical therapists (including one who practiced acupuncture and one involved in clinical research), an occupational therapist, and a patient with RA. The Ottawa Panel consisted of these 9 experts and all members of the OMG.

One OMG member assembled a research and support staff with expertise in meta-analyses, rheumatology rehabilitation interventions, research methods, or the development and assessment of EBCPGs. The OMG then established a priori a set of inclusion criteria for the study designs, subject samples, interventions, and outcomes to allow the research staff to select the most relevant material as evidence of the effectiveness of therapeutic exercise and manual therapy. The OMG also reviewed the inclusion criteria to ensure that the approach to the study selection was reproducible and systematic. This a priori protocol guided separate systematic reviews of the literature for each intervention. The research staff reviewed articles and created evidence tables for them, which the 9 clinical experts received in preparation for their meeting with the OMG. These tables were used as the basis for making the recommendations.

RATING SCHEME FOR THE STRENGTH OF THE RECOMMENDATIONS

The recommendations were graded by their level (I for randomized controlled trials [RCTs], II for nonrandomized studies) and strength (A, B, C+, C, or D) of evidence.

Grade A: Evidence from one or more RCTs of a statistically significant, clinically important benefit (>15%)

Grade B: Statistically significant, clinically important benefit (>15%) if the evidence was from observational studies or controlled clinical trials (CCTs)

Grade C+: Evidence of clinical importance (>15%) but not statistical significance

Grade C: An appropriate outcome was measured in a study that met the inclusion criteria but no clinically important difference and no statistical significance were shown

Grade D: Evidence from one or more RCTs of a statistically significant benefit favoring the control group (<0%: favors controls)

COST ANALYSIS

A formal cost analysis was not performed and published cost analyses were not reviewed.

METHOD OF GUIDELINE VALIDATION

Comparison with Guidelines from Other Groups
External Peer Review

DESCRIPTION OF METHOD OF GUIDELINE VALIDATION

The guidelines were sent to the external experts for review. To judge clinical usefulness, the 20 positive recommendations also were sent to 5 practitioners for feedback. Practitioners were selected from clinical settings in the Ottawa and Toronto regions and were a physical therapist, an occupational therapist, a physiatrist, a family physician, and a rheumatologist, all of whom were currently working with patients with rheumatoid arthritis (RA). Practitioners were asked 4 questions for each guideline: whether the recommendation was clear, whether the practitioners agreed with the recommendation, whether they felt that the literature search on therapeutic exercises and intensity of rehabilitation was relevant and complete, and whether the results of the trials in the guidelines were interpreted according to the practitioners' understanding of the data. Results of this survey are shown in the "Results" section of the original guideline document.

The development of the draft Evidence-Based Clinical Practice Guidelines (EBCPGs) prepared for the expert members was in concordance with Appraisal of Guidelines Research and Evaluation (AGREE) criteria. Using AGREE (www.agreecollaboration.org), 2 trained physical therapists assessed the Ottawa Panel EBCPGs for rheumatoid arthritis (RA). This tool consists of 6 dimensions measured on a 4-point scale, where 1 represents "strongly agree" and 4 represents "strongly disagree." The dimensions are: (1) purpose, defined as overall objectives that described the potential impact of a guideline on society and populations of patients; (2) stakeholder involvement, defined as the extent to which the guideline represents the views of its targeted users; (3) rigor of development, which deals with the process used to gather and synthesize the evidence and with the methods to formulate the recommendations and to update them; (4) clarity and presentation, which refers to the language and format of the guideline; (5) applicability, which relates to the likely organizational, behavioral,

and cost implications of applying the guideline; and (6) editorial independence, which refers to the independence of the recommendations and acknowledgment of possible conflict of interest from the guideline development group. The EBCPGs obtained a very high score for dimensions 1 (purpose), 2 (stakeholder involvement), 4 (clarity), and 6 (editorial independence), with lower scores for dimensions 3 (rigor of development) and 5 (applicability). On the University of Ottawa School of Rehabilitation Sciences Web page (<http://fss.hs.uottawa.ca/EBCpg/english/>) precise results are currently available, and decision aids with detailed clinical application will soon be available. The rigor of development was low because of poor reporting of side effects and risks, which were not reported in the primary trials and therefore not included in the EBCPGs. The applicability was low, particularly in identifying potential organizational barriers, cost implications, and methods of applying and monitoring the guidelines.

The recommendations on therapeutic exercise are in concordance with all other existing guidelines: (Ontario Program for Optimal Therapeutics, American College of Rheumatology, American Pain Society, American Occupational Therapy Association).

RECOMMENDATIONS

MAJOR RECOMMENDATIONS

Each recommendation is followed by recommendation grades (Level I or II and A, B, C+, C and D). Definitions of the recommendation grades are presented at the end of the "Major Recommendations" field.

Shoulder functional strengthening (strengthening involving movement useful in daily activities) versus control, level II (controlled clinical trial [CCT], n = 28) (Mannerkorpi & Bjelle, 1994): Grade C for activities of daily living (ADL), pain, and range of motion (ROM) at 2 months (no benefit). Patients with chronic rheumatoid arthritis (RA), functional class I or II, and shoulder pain.

Hand functional strengthening versus control, level II (CCT, n=41)(Hoenig et al., 1993): Grade C for ROM and grip force at 3 months (no benefit). Patients with chronic RA and functional class II or III.

Knee functional strengthening versus control, level I (randomized controlled trial [RCT], n = 35) (McMeeken et al., 1999): Grade A for pain at 6 weeks (clinically important benefit); grade C for function at 6 weeks (no benefit). Patients with seropositive or seronegative inflammatory RA requiring long-term medication.

Whole-body functional strengthening versus control, level II (CCT, n = 312) (Ekblom et al., "Effect of short-term physical training: I," 1975; Ekblom et al., "Effect of short-term physical training: a six-month follow-up," 1975; Hakkinen, Hakkinen & Hannonen, 1994; Harkcom et al., 1985; Kirsteins, Dietz, & Hwang, 1991; Minor & Hewett, 1995; Nordemar et al., 1981; Noreau et al., 1995; Rintala, Kettunen, & McCubbin, 1996; Van Deusen & Harlowe, 1987): Grade B for sick leave and lower-limb muscle force at 8 years (clinically important benefit); grade C+ for swollen joints at 2 months. Grade C for the following: pain at 2 months

and 8 years; function at 3 and 6 months; ROM at 3, 6, and 12 months; number of inflamed joints at 2 months and 8 years; grip force at 2, 6, and 12 months; leg muscle force at 8 weeks; and walking capacity at 6 weeks and 6 months (no clinically important benefit). Patients with diagnosis of RA and functional class I, II, or III.

Whole-body, low-intensity functional strengthening exercises (group dynamic exercises) versus instructions for home, level I (RCT, n=100) (van den Ende et al., 1996): Grade C for pain, function, swollen/tender joints, and global patient (patient's assessment of overall disease activity or improvement (Philadelphia Panel Evidence-Based Clinical Practice Guidelines, 2001) at 3 and 6 months (no benefit). Patients with RA (chronic stage).

Physical activity versus bed rest, level I (RCT, n=145) (Alexander, Hortas, & Bacon, 1983; Lee et al., 1974; Mills et al., 1971): Grade A for grip force at 3 months (clinically important benefit); grade C for pain, tender joints, function, ROM, swollen joints, and time to walk 15.24 m (50 ft) (no benefit demonstrated). Patients with RA (chronic stage).

Whole-body, low-intensity exercises (individualized) versus control (written instructions for home exercises), level I (RCT; n=100) (van den Ende et al., 1996): Grade A for change in function at 3 months (clinically important benefit); grade C+ for pain relief at 3 months (clinically but not statistically important benefit); grade C for changes in tender/swollen joints, joint mobility, and muscle force at 3 and 6 months (no benefit). Patients with RA (chronic stage).

Whole-body, high-intensity exercises (group) versus control (written instructions for home exercises), level I (RCT, n=100) (van den Ende et al., 1996): Grade C for pain, function, joint mobility, muscle force, and swollen/tender joints at 3 and 6 months (no benefit). Patients with RA (chronic stage).

Whole-body, low-intensity exercises (group) versus whole-body, high-intensity exercises (group), level I (RCT, n=100) (van den Ende et al., 1996): Grade A for pain at 6 months (clinically important benefit favoring low intensity); grade C+ for function at 3 months (clinically but not statistically important benefit); grade C for joint mobility, muscle force, and swollen/tender joints at 3 and 6 months (no benefit). Patients with RA (chronic stage).

Definitions:

The recommendations were graded by their level (I for RCTs, II for nonrandomized studies) and strength (A, B, C+, C, or D) of evidence.

Grade A: Evidence from one or more RCTs of a statistically significant, clinically important benefit (>15%)

Grade B: Statistically significant, clinically important benefit (>15%) if the evidence was from observational studies or CCTs

Grade C+: Evidence of clinical importance (>15%) but not statistical significance

Grade C: An appropriate outcome was measured in a study that met the inclusion criteria but no clinically important difference and no statistical significance were shown

Grade D: Evidence from one or more RCTs of a statistically significant benefit favoring the control group (<0%: favors controls.)

CLINICAL ALGORITHM(S)

None provided

EVIDENCE SUPPORTING THE RECOMMENDATIONS

REFERENCES SUPPORTING THE RECOMMENDATIONS

[References open in a new window](#)

TYPE OF EVIDENCE SUPPORTING THE RECOMMENDATIONS

The type of evidence is identified and graded for each recommendation (see "Major Recommendations").

BENEFITS/HARMS OF IMPLEMENTING THE GUIDELINE RECOMMENDATIONS

POTENTIAL BENEFITS

Appropriate use of therapeutic exercises for the treatment and rehabilitation of adults with rheumatoid arthritis

POTENTIAL HARMS

- Physical activity as compared with bedrest may have negative effects on outcomes such as pain, function, range of motion (ROM), number of tender or swollen joints, and time to walk 15.24 m (50 ft).
- The effects of high-intensity exercise on pain may be a concern.

QUALIFYING STATEMENTS

QUALIFYING STATEMENTS

The Evidence-Based Clinical Practice Guidelines (EBCPGs) developed by the Ottawa Panel have some potential limitations due to methodological weaknesses. Although the included trials were selected based on well-established inclusion and exclusion criteria, selection was performed by occupational therapist and physical therapist students. Potential omission of studies due to reviewer inexperience could have led to selection bias. Consultation with a third reviewer and the use of the panel of senior clinical experts may have compensated in part for this potential methodological flaw. The EBCPGs also are limited by the inclusion and exclusion criteria for the included studies. For example, some reports of

randomized controlled trials (RCTs) did not specify if the study sample included individuals in acute or chronic stages of rheumatoid arthritis (RA). Additionally, some studies lacked details about the specific characteristics of the exercise intervention such as intensity. This lack of specificity could be problematic for future clinical implementation of the guidelines, especially for the whole-body functional strengthening recommendation.

IMPLEMENTATION OF THE GUIDELINE

DESCRIPTION OF IMPLEMENTATION STRATEGY

The Ottawa Panel is planning to implement these guidelines in the Arthritis Rehabilitation and Education Program of The Arthritis Society of Ontario.
